This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Ethnopharmacology in the Upper Guadiana River area (Castile-La Mancha, Spain)

Relevance of the different kingdoms and types

Wetlands as a source of medicinal ingredients and foci of pathologies

Geographical patterns of medicinal ingredients (188 plant species, 20 animals and 12 minerals)

Table 1. Medicinal ingredients and uses, Kingdom: Animalia.

ABSTRACT:

Ethnopharmacological relevance: Determining traditional remedies for human pathologies is relevant, when compared with the standard materia medica of the pharmacopoeias and dietary supplement databases, because we can assess the species and uses that have been previously studied and target understudied species for further pharmacological investigation.

Background: The aim of this study was to systematically record and analyze medicinal uses of natural resources (Plantae, Animalia, Fungi and minerals), mostly local, in the territories adjoining the upper Guadiana River and its tributaries.

We were particularly interested in recording resources and pathologies linked to wetland areas, especially in the National Parks Las Tablas de Daimiel and Cabañeros. Wetlands are interesting because they present a double face in relation with human health: Wetlands furnish hydration, safe water, nutrition, and medicinal resources; are places from which people derive their livelihood. However wetlands are also sites of exposure to pollution or toxicants, and infectious diseases; and sites of physical hazards.

We wanted to identify procedures for preparation of medicinal formulae and routes of administration. We also intended to detect whether a geographical pattern exists or not in our records in relation to the use of local resources.

Methods: We used semi-structured interviews with one-to-one informants or groups, from 1998 to 2018. Raw data were introduced in a Firebird database and analyzed. To identify ingredients and pathologies we consulted local floras and epidemiological literature. Finally, we compared documented pathologies, remedies and ingredients in the historical context of medicinal uses of natural resources in Castile-La Mancha and especially in Ciudad Real.

Results: 126 pathologies and 220 species furnishing ingredients have been recorded from the interviews. In total, 188 are plants and 20 animals. The most commonly used species include *Malva sylvestris*, *Phlomis lychnitis*, *Genista tridentata* and *Thymus mastichina*. Most records refer to flowers, or fruits, of locally available plant species, classified as Mediterranean, European or widespread that belong to the Lamiaceae, Compositae or Leguminosae. Ingredients which are collected in open shrublands,

known as “*garrigue*”, and dry grasslands furnish a relevant proportion of records while the imported ingredients remain marginal. The contribution of wetlands, riverine habitats and irrigated fields and gardens as a source of medicinal resources is 36% of the records. It is relatively high considering its limited presence in terms of total extension within the study area. The most frequently reported diseases are respiratory, gastrointestinal, dermatological and infectious or parasitic.

Conclusions: Along the Guadiana River in the Ciudad Real province exists a wide and deep knowledge of traditional remedies for the treatment of common pathologies, based fundamentally on the use of local flora, fauna and mineral resources. The uses and ingredients documented are useful for further pharmacological investigation to improve health care for a wide range of pathologies.

1 Introduction

In rural areas of Castilla-La Mancha (Spain) there were several systems of alternative and / or complementary medicine since at least the fifteenth century, along with the official academic system accepted by the authorities (Blázquez, 1985 and 1989; Rivera et al. al., 2017). These systems ended up being fused in a complex of practices and beliefs during the XIX and XX centuries, in what is called "Folk Medicine" (Baer et al., 2006, Kuschick, 1989 and 1995, Press, 1973).

The folk medicine of Castile-La Mancha is part of the Mediterranean TKS (Traditional Knowledge System). This involved the use of, essentially, local resources for the subsistence of rural population, small towns and cities and gradually faded since the 1950s (Rivera and Obón, 1996). Ethnobotany and ethnopharmacology of Castile-La Mancha has been subject of different studies, articles and books (Fajardo et al.,

2000, 2007; Rivera et al., 2005; 2006; Rubio et al., 2013; Verde 2002; Verde et al., 1998, 2000, 2008).

The Guadiana River crosses the province of Ciudad Real in Castilla-La Mancha. The main course of the Guadiana River and its tributaries form a group of wetlands with peculiar characteristics that were, during centuries, habitats of medicinal resources, but also for diverse vectors of diseases and pathogenic organisms (Fisac, 1905 a). Wetlands present a double face in relation with human health: they are contributors to hydration, safe water and nutrition; places from which people derive their livelihood; settings for mental health and psycho-social well-being; places that enrich people's lives, enable them to cope and to help others; and sites from which medicinal and other products can be derived; but they are also sites of exposure to pollution or toxicants, and to infectious diseases; and sites of physical hazards (Dale & Connelly, 2012; Horwitz & Finlayson, 2011; Zimmerman, 2001).

Wetlands are the loci for communicable diseases classifiable in two main categories: vector-borne (vectors of human disease can be snails, mosquitoes, and flies among others), and water-borne (produced by cyanobacterial toxins, tapeworm, *Fasciola*, bacteria, protozoa and viruses) (Horwitz et al., 2012). Hunting species, such as deer, are abundant in the area and, increasingly, host pathogens, such as the Hepatitis E Virus (Boadella et al., 2010). In parallel, preventive measures have led to a decrease in the incidence of hepatitis A, B and C infections (Pachón and Shouval, 2007).

Infectious diseases were relatively frequent until the mid of 20th century and occasionally reached the level of epidemic, as measles, typhoid fever, tuberculosis, malaria, diphtheria, anthrax, and influenza (Castejón, 2015; Fisac, 1904, Fisac, 1905 a, Fisac 1905 b). The Spanish flu (H1N1 influenza virus) deeply impacted Daimiel in the years 1918 to 1920 (García-Consuegra, 2013). Picó (1977) mentions in the adjacent San Clemente town: petechiae, smallpox, measles, whooping cough, and different malaria types. Most of these were eradicated during the 20th century through systematic vaccination and the elimination of such vectors as *Anopheles* mosquito.

Medicinal plants were, and still are, abundant in the area (Fisac, 1905 a; Mestre, 1865; Porres et al., 1986; Torres, 1821). Mineral medicinal resources in this area are diverse, ranging from salt mines (Carrasco and Hueso, 2006; Zubiri, 2010) to springs of carbonated water ("*hervideros*") (Bañares, 1820; Mestre, 1865; Torres, 1821).

Numerous healers, notably women, existed in this area, in particular in the zones of Daimiel and Cabañeros, (Fig. 1), which attracted the interest of the Inquisition tribunals from the 15th to the 19th centuries (Cirac, 1942; Longobardo et al., 1997). Here several places are called “*Las Curanderas*” (the female healers) (BOP, 2008) because of the existence of them in that locality even in modern times.

Still in the second half of the 20th century (García, 2002) several healers, mainly women, lived in the Motilla, Herrera and adjacent streets of Daimiel. They were and continue to be consulted by sick people from the towns and villages of La Mancha. However, although this practice continues to exist in 2019, it is always difficult to interview such healers exhaustively since they are reluctant to share information with foreigner people, like most of us, who identified themselves as researchers at the university or, even, with local people who say that the results of this research will be published.

Studying ethnopharmacology in this area is interesting given the particular environmental constrains for resources and pathologies associated to wetland and riverine habitats. Most studies available for the area are of general ethnobotany and lack of detailed ethnopharmacological information especially concerning preparation and administration of medicines. Another aspect missing in the literature for the area is the ensemble of ingredients of animal and mineral origin. Finally, the existence of historical evidence for medicinal resources used in this area, although fragmentary, offered the opportunity to identify their persistence, losses and changes comparing with modern ethnopharmacological data.

This paper has seven objectives:

1. Recording traditional formulas of folk medicine which were used during the second half of the 20th and the beginnings of the 21st centuries by the inhabitants of the Upper Guadiana Rivera area. It consists of systematically interviewing persons who are likely hold local TK (Traditional Knowledge), in particular about ethnopharmacology. We focus on the remedies and their formulations that have been used by the interviewees or their parents in the area.
2. Another objective is to determine the diseases mentioned by our informants and their relative importance in terms of remedies recorded.

3. We also intend to identify in terms of scientific nomenclature the different ingredients, not only those of plant origin but also those of animal or mineral origin. We expect to quantify the relative relevance of plants, animals and minerals and set focus on the key species widely used which merits further investigation.
4. We have special interest in determining the relevance in the area of local resources and especially of plants and animals associated to wetlands and riparian habitats.
5. We want to identify procedures for preparation of medicinal formulae and routes of administration.
6. We intend to detect whether a geographical pattern exist or not in our records in relation to the use of local resources.
7. Finally, we aim to compare documented pathologies, remedies and ingredients in the historical context of uses of medicinal plants in Castile-La Mancha and especially in Ciudad Real.

Our first hypothesis is that the repertory of medicinal ingredients (not only plants but also of zoological and mineral origins, or even synthetic pesticides) in a determined period, and zone, and their relative frequency, in terms of medicinal uses or presence in formulations, provides a unique sequence that represents the characteristics of each medical-pharmaceutical system (Rivera et al., 2017). In this case the period and area are: 1998-2018 and the Upper Guadiana River.

Therefore we hypothesize that ingredients and pathologies related to wetlands and riverine areas will play a significant role in the local *materia medica*, and that historically documented practices will be reflected in the information recorded given the long tradition these have in the Guadiana River area. Ethnopharmacology can be approached in a diachronic perspective, and historical data about local therapeutics can help to understand the dynamism of traditional knowledge on pathologies and medicinal resources. Lastly we hypothesize that the repertory of uses and species will offer interest for further pharmacological investigations.

2 Material and Methods

2.1 Data collection

2.1.1 Geographical coverage

This paper focuses on the area covered by the Guadiana River along Castilla-La Mancha region (central Spain) in the Ciudad Real Province (Fig. 1).

Fig. 1 approx. here.

The Guadiana River stretches along 818 km in southern Spain and Portugal with an average flow in the Spanish stretch of 26 m³ /s. Part of its course is subterranean and spring from its three main sources: Pinilla River, Ruidera Lagoons and “*Ojos del Guadiana*” from there it runs on surface to its mouth between Ayamonte (Spain) and Vila Real do Santo Antonio (Portugal). This supposes that between Ruidera and Ojos the presence of wetlands and riverine habitats is scarce on account of disappearing water from the surface.

Our ethnopharmacological research concentrates in the areas neighboring the Upper Guadiana River, and its tributaries (Azuer, Cigüela, Estena, and Zán cara River), especially in two National Parks, those of Cabañeros and Las Tablas de Daimiel, and the Natural Park of Lagunas de Ruidera in Ciudad Real province (Spain) and close localities of Albacete, Cuenca and Toledo Provinces (Fig. 1).

Population of the province concentrates in the localities of Ciudad Real, Puertollano, Tomelloso, Alcazar de San Juan and Valdepeñas. The municipalities where our research is concentrated have less than 1000 inhabitants each, with the exception of Daimiel. Density of population is particularly low in the area of Cabañeros with 1.4 to 3 inhabitants per km². The proportion of aged population (>65) reached in 2008 48.5 % in localities such as Fontanarejo. Ageing is a generalized phenomenon in smaller nuclei of population. The incorporation of young foreigners, fundamentally from Rumania, is in part compensating the loss of population in the northern part of the province. By 2001 illiteracy reached a 25.5% for the whole province with peaks in Fontanarejo (89%) and Granátula de Calatrava (68%). Agriculture is the main occupation of the population in the area with values of 53% in Fontanarejo, 44% in Arroba de los Montes and 42 % in Navas de Estena (BBVA, 2008).

We draw maps using GMT (2014).

2.1.2 *Sequence of the study*

We followed a logical sequence for recording, processing and standardizing data which is summarized in Fig. 2.

Fig. 2 approx. here.

Our study is based on c. 103 interviews, individual or with groups of people. The field work took place from 1998 to 2018 and comprised 46 localities (Fig. 3) and 141 informants from which 98 were independent (neither interviewed simultaneously nor belonged to the same family). The majority of the informants were men (113), while the women were only 24, other records were obtained by interviewing couples and, finally, some records were obtained from interviews with groups of three to eleven people.

We must mention that the interviews carried out generally covered a wide range of ethnobiological topics, of which, in the present work, only the records related to human medicine are analyzed.

We tried to cover the main areas (Cabañeros and Tablas de Daimiel) as continuously as possible throughout the investigation period, with some interruptions. The discontinuities are, unfortunately, often due to the death of our informants, given their ages.

Fig. 3 approx. here.

2.1.3 *Data from other ethnobotanical and historical sources*

In order to compare our results with other sources of evidence, we started with all the available manuscripts that were consulted to register medical formulations or references to medicinal plants and their uses. Fragmentary information on pathologies and their remedies in the 16th century is found in the *Relaciones Topográficas de Felipe II* (Campos, 2009). The Cardenal Lorenzana, archbishop of Toledo from 1772 to 1800, promoted the inventory of resources, climate, morbidity and mortality causes of the

different municipalities of his dioceses (Porres et al., 1986); some of the reports include information on local remedies.

We, particularly, have found relevant information in the “*Topografías Médicas*”. These are studies, carried out by regular doctors, of specific places and their populations, which are approached from a hygienic-sanitary perspective and that include, in general, the physical description of the locality: situation, climate, soil, hydrography, and the environment, flora and fauna; historical background, physical temperament and moral character of its inhabitants, their customs and living conditions, demographic movements and dominant pathologies (Casco, 2001). Among these *topografías* it was particularly helpful the manuscript of Doctor Gaspar Fisac, dated 1905, describing Daimiel (Fisac, 2005 a; RANME, 2018).

The ethnobotanical studies available with data on localities within the area include: Montes de Toledo (Blanco, 2004, Leblic 1988a, 1988b and 1994); south of Campo de Calatrava (Molero et al., 2001); Villarrubia de los Ojos (Arauzo et al., 2001); and, from the adjacent provinces: Badajoz (Vázquez et al., 1997), Barros Area (Vázquez et al., 1997), Fuenlabrada de los Montes (Blanco et al., 2000), Guadiana del Caudillo (Vallejo et al., 2005; 2008), and the area of Cañada Real Segoviana (Toledo) (Rojo, 2011).

The materials consulted for comparison with our interviews, which are useful due to the similarities of the areas in terms of vegetation and habitats, were from Andalusia (Benítez et al., 2010); and southern and central Portugal, in particular Arrabida (Novais et al., 2004) and Sao Mamede (Camejo et al., 2003).

2.1.4 *Systematization of data*

We recorded remedies, viz. formulas, each one with ingredients (single or in mixtures), forms of preparation and administration which were addressed to the treatment of one or several pathologies. For the purpose of our analyses formulas were broken down in their different ingredients. We name “use” (simplified for “use of the ingredient”) to each single combination of ingredient – preparation – administration and pathology. Therefore, we focus on the uses of each ingredient, although another approach is to establish the focus on mixtures (Gras et al., 2018). Each use can be recorded once or repeatedly, thus “record” is for us each “use” given by an independent informant. For this purpose we consider groups of people or families interviewed

together dependent informants represented in each case by one single independent informant (Tables 1 to 5).

The information collected from the informants during the interviews was introduced into a database. Both database design and specific software have been created to manage the ethnobiological information documented in the National Parks of Cabañeros and Tablas de Daimiel, and neighboring areas of the upper Guadiana River.

Firebird has been used as a Database Manager System (Firebird, 2018), which is Open Source, and therefore of free distribution. The software has been created using Delphi® 10.2 Tokyo Professional (Delphi, 2018). From this database an Excel compatible output was generated. Then a structured sheet with crude data of human medicine was generated. This sheet was filtered to generate a specific sheet on resources used to treat pathologies in humans. The sheet generated was again manually compared with data systematized from Montes de Toledo field work by Verde, Rivera and Obón from 1997 to 2002 (Verde, 2002) for missing data resulting in a final corrected sheet which consisted in independent records characterized with 17 variables (1 Standardized Kingdom, 2 Standardized Family, 3 Standardized Scientific Name, 4 Provenance, 5 Vernacular name, 6 Voucher, 7 Locality, 8 Standardized Locality, 9 Part standardized, 10 Preparation, 11 Administration, 12 Emic Use, 13 ICD_10, 14 Standardized ICPC 2e7.0 Pathology, 15 Broad Group of use, 16 Informants, 17 Habitat). In order to standardize vernacular nomenclature, especially for vernacular names of diseases and of ingredients of medicines some dictionaries were created in Excel, which were then applied to the automatic generation of the final text.

2.2 *Standardization of data*

Adherence to data standards will facilitate data consistency, exchange of data and comparative analyses. A number of botanical and taxonomic standards have been developed over the years, some of which could be incorporated into ethnopharmacological databases (Heinrich et al., 2009; Rivera et al., 2014).

2.2.1 *Inclusion criteria*

Regarding the inclusion criteria for these medicinal recipes, we included those recipes addressed to the treatment of human pathologies whose equivalences are defined by ICD 10 (2018) or eCIEMaps (2018). We excluded, therefore, veterinary formulas and references to toxic plants, poisonous animals and mineral substances of

known toxicity. This set constitutes sufficient material for a separate study. General dietary prescriptions not related to specific pathologies were also excluded from here.

2.2.2 *Dictionary of diseases*

To interpret the vernacular names of pathologies Ballano (1805-1807), DRAE (2017), Kuschick (1995), and Sánchez (2015) were consulted.

The pathologies were interpreted and named using two generalized coding systems for medical problems: ICPC-2 and ICD-10.

The International classification of primary care (ICPC-2) is an epidemiological tool for use by the primary care provider during the consultation (Direktoratet for e-helse, 2018) with relatively reliable results even when used by trained non-medical coders (Luna et al., 2001).

The International statistical classification of diseases and related health problems 10th (ICD-10) (WHO, 2018), and the Spanish version of the latter (eCIEMaps, 2018), is the foundation for the identification of health trends and statistics, globally, and the international standard for reporting diseases and health conditions (WHO, 2018). In this paper adscription to standard categories reflects our tentative interpretation of the reported pathologies.

Each classification system presents a structure that is its own and distinct from the rest, therefore some categories may differ for the same emic disease. Hence there is not an optimal option (Staub et al., 2015). Concerning pharmacological issues we followed the 17 broad-use categories proposed by Staub et al. (2015) for studies addressed to the development of plant-derived drugs (Tables 1 to 5).

2.2.3 *Dictionary of ingredients*

We collected voucher-specimens of plants and fungi which were deposited in the herbarium ALBA (Universidad de Castilla La Mancha, Albacete, Spain) as a rule, excepted the older samples which were deposited in MUB (Universidad de Murcia, Murcia, Spain). Further details on these herbaria are available at NYBG (2019). For animals we took photographs which are available at the repository of images (<http://ethnobiowetlands.es/etnofauna/>) of the “*Etnobiología de los humedales*” portal. The identity of plant ingredients was determined based on the collected specimens and with the use of existing standard regional floras, and the names were verified with the botanical literature available at BHL (2018), the WHO (2015) monographs, and

databases: Anthos (2018), Euromed (2011), Tropicos (2018), GRIN (2018), IPNI (2018), NCBI (2018), Fitoterapia.net (2018) and, most importantly, nomenclature was standardized according to The Plant List (TPL 2018) and to the procedures suggested by Rivera et al. (2014).

Concerning groups of plants and other ingredients with similar qualities and uses (i.e. ethnotaxonomic species complexes or pharmaceutical names of drugs), these were identified collectively using an inclusive scientific taxon name.

The drugs of zoological and mineral origin appear, with different relevance, in almost all the localities studied. The animals were identified in the field with our informants, according to the documents of the Fauna Ibérica project (Merino, 2019), but no samples were taken due to the capture restrictions imposed by Spanish legislation and because, lately, the use of animals is decreasing. We preferred photography instead of capturing animals. Specific literature consulted includes, for blister beetles (Meloidae), Percino et al. (2013).

We identified the mineral ingredients with the help of García-Guinea & Martínez (1992) and Maraver (2004). We updated nomenclature according to the New International Mineralogical Association List of Minerals (IMA, 2016, 2018) and Pubchem (2018) and the ingredients of zoological origin using the Global Biodiversity Information Facility (GBIF 2018) and García and Gisbert (2018).

The scientific names of biological species, with authorities, have been listed in alphabetical order of families, genera and species, in Tables 1, 2 and 5. For the species not mentioned there, the standardized acronyms of the authors have been added to the scientific names in the main text, when they appeared for the first time.

2.2.4 *Geographical origin and habitats of ingredients*

Each ingredient of the analysis was identified and classified in terms of the main biogeographical profiles and zones of origin divided in Widespread, Mediterranean, Europe, Spain, Asia, America, Pacific islands, Northern and Eastern Hemisphere, according to Rivera et al. (2012) and GBIF (2015).

Habitats were determined during the field work and collection of voucher specimens. These are named according to EUNIS (2018). The EUNIS habitat classification is a comprehensive pan-European system to facilitate the harmonized description and collection of data across Europe through the use of criteria for habitat

identification. It is hierarchical and covers all types of habitat from natural to artificial, from terrestrial to freshwater and marine (EUNIS, 2018).

2.3 Data Analysis

2.3.1 Ordination and classification of localities based on the lists of ingredients

In order to determine how different these 46 localities are, considering as a reference the 220 species documented (see chapter of results), we calculated the pairwise differences between samples in form of a dissimilarity matrix. However, we excluded ingredients recorded in one single locality and localities with less than 4 ingredients. Thus the filtered crude matrix was reduced to 31 localities and 139 species. Data were considered for each locality over the whole period 1998-2018. We adopted this approach since splitting into shorter periods produced unmanageable too small subsamples.

The crude matrix of presence/absence of ingredients was used to compute a dissimilarity matrix using Darwin 6 V.6.0.9 (2015-04-15) (Perrier, Flori & Bonnot, 2003; Perrier & Jacquemoud-Collet, 2006). The Sokal-Sneath dissimilarity index was calculated (un2) ($d_{ij} = 2(b+c) / a+2(b+c)$), where d_{ij} is the dissimilarity between samples i and j , a : number of variables where $x_i = \text{presence}$ and $x_j = \text{presence}$, b : number of variables where $x_i = \text{presence}$ and $x_j = \text{absence}$ and c : number of variables where $x_i = \text{absence}$ and $x_j = \text{absence}$. Dissimilarities are even and are Euclidean distances. The dissimilarity is =0 for two samples sharing the 139 species and =1 for two samples which present 0 species shared. This index concerns 'presence/absence' data where only 'presence' modality is informative, modality 'absence' expressing mainly an absence of information. These two modalities are not symmetrical and their exchange leads to a completely different dissimilarity value. This index considers that a common absence for two units is uninformative to measure their dissimilarity (Perrier & Jacquemoud-Collet, 2006). Therefore, similarity here reflects the number of coinciding species and dissimilarity is inversely proportional to this.

These pairwise dissimilarities can be represented in a multidimensional space, but, in order to obtain meaningful graphic representation of these relationships in a two-dimensional plane, we used cluster analysis (Kovach, 2007).

We used the agglomerative hierarchical method that arranges the clusters into a hierarchy so that the relationships between different groups are apparent. Minimum variance clustering (Ward's method) focuses on determining how much variation is within each cluster. In this way, the clusters will tend to be as distinct as possible, since the criterion for clustering is to have the least amount of variation (Kovach, 2007).

Ward's method produces a single tree, however, in order to further reducing the uncertainty in the structure of the tree, we used a bootstrapped matrix (500 bootstraps) and a tree construction method (weighted neighbor joining) (Saitou & Nei, 1987) that uses the trees inferred from these bootstrapped dissimilarities to assess the uncertainty of the tree structure. These methods provide a representation of the relationships among localities.

3 Results and discussion

3.1 Knowledge of the informants

The knowledge recorded during the interviews with our informants is highly variable: the number of medicinal records per informant ranges from 1 to 109 (on average 8.5), species used range from 1 to 48 (on average 6.7), and pathologies treated vary from 1 to 40 (on average 5.2). Over 50% of informants furnished 1 to 5 records, describing 1 to 5 pathologies and ingredients (Fig. 4). It is worth to notice here that we quantify the knowledge that the informants were willing to share with us and we were able to record using the semi-structured interviews but not their real knowledge. This is of application in most ethnobiological studies.

It is appropriate here to recall that our interviews covered a wide range of subjects and therefore we usually recorded also information on veterinary, agricultural diversity and practices, food and crafts, together with specific recipes for pathologies in humans. We did not proceed to monographic interviews with our informants on health issues. Interview sessions lasted between half and three hours and key informants were repeatedly interviewed.

The low proportion of women interviewed is related not to our sampling strategy, but to the difficulty of finding in this area people who are willing to be interviewed. This could be interpreted in terms of the role played locally by women as healers and the tradition of hiding this knowledge. For instance, "Las Curanderas" (the female healers) is the official name for a place and a local road in Daimiel (BOP, 2008) in the

vicinity of Puente Navarro. In this area in 2018 still lived female healers, but they were uniquely willing to talk about ornamental plants of their home gardens, and especially eluded to talk with us of healing practices. There is a long history of confrontation between official medicine and female healers in this region which could explain their reluctance to recognize their condition and to reveal and share their knowledge (Blázquez, 1985; Cantacalero, 1924; Fernández, 2014; Gómez, 2018; Moya & Fernández, 2016; Nieves, 2008; Salvador, 2015; Schmitz, 2016).

Concerning gender and quantity of information recorded, it was, on average, slightly higher from women (10.7 records) than from men (9.4). It is worth to note that, when the interviews involved simultaneously men and women, often husband and wife, the results were better (14.7 records on average).

Another aspect to consider is that the way in which questions are asked can lead to biased or incomplete responses. For example, during the first five years we used a general pattern of nonspecific questions where malaria was never cited. But when several years later we asked the same informants, that we had interviewed for years, about malaria (specifically about "*tercianas*" and "*paludismo*"), a disease that was declared eradicated in the 1960s, several mentioned various remedies experienced by themselves.

Fig. 4 approx. here.

We must emphasize that the profile of the knowledge of the Spanish population in the rural areas is suffering in the 21st century a profound change in the sense of a deep loss of knowledge associated with a trivialization (Rivera et al. 2017). This has led to the Spanish authorities to start the Spanish inventory of traditional knowledge related to biodiversity (Pardo et al., 2012, 2014, 2018a, 2018b, 2018c). However, the data collected in the villages of Ciudad Real from 1998 to 2018 still reflect a rich and diversified local culture, little influenced by globalization. This explains the high proportion of locally produced species.

3.2 Diseases

3.2.1 Relevant pathologies

We documented during our field-work 126 different ICD-10 types of pathologies, corresponding to 88 ICPC-2 diseases (Tables 1 to 5). Pathologies most frequently

registered belong to the categories of respiratory, gastro-intestinal, dermatological and infectious and parasitic (Fig. 5).

It is worth noting here that the use of ICD-10 or, alternatively, ICPC-2 to classify diseases leads to minor changes in the overall results (Tables 1 to 5), although most of the emic pathologies are classified in a similar way, with slight lexical variants, especially those that present a higher incidence (Fig. 5).

The common cold was the most frequent respiratory problem and was treated by our informants (Fig. 5) with decoctions or numerous herbal teas, alone or as mixtures, drinks or externally applied as poultices. These include fennel (*Foeniculum vulgare*), aniseed (*Pimpinella anisum*), mustard (*Sinapis alba*), *Paronychia argentea*, *Cistus ladanifer*, *Achillea ageratum*, *Anthemis arvensis*, *Ephedra major*, *Lavandula pedunculata*, *Mentha pulegium*, *Rosmarinus officinalis* and others. Some of these species and uses were previously documented by Blanco (2004) and Leblic (1994) in the province of Toledo. Leblic (1988b) documented the use of *Agrimonia eupatoria* in Montes de Toledo to treat sore throat, which we did not register.

The wounds were often reported (Fig. 5) and cured (Tables 1 to 2) with animal and fungal products, such as honey, heron feathers, boiled droppings of donkey or hen, human urine, snake skin, bacon or fungal spores.

Wounds were also treated with salt (Table 3), and numerous plant species (Table 5) such as reeds (*Arundo donax*), pimpinella (*Sanguisorba minor*), and elderflower (*Sambucus nigra*) tea, alkanet (*Alkanna tinctoria*) root macerated in olive oil, *Retama sphaerocarpa*, *Chelidonium majus*, mallow (*Malva sylvestris*) or alfalfa (*Medicago sativa*). *Paronychia argentea*, *Thymus mastichina*, *Thymus zygis* or *Salvia officinalis* were reported as useful for wound washing (Table 5). Decoctions of *Cistus crispus* or *Cistus ladanifer*, *Centaurea melitensis* or *C. ornata*, *Lavandula stoechas* or *Rosmarinus officinalis*, or of *Quercus rotundifolia* bark were also cited. *Achillea ageratum*, macerated in brandy or fried in olive oil, leaves of *Hylotelephium spectabile*, and resin of *Juniperus oxycedrus* were also used as remedies for wounds, externally applied (Table 5).

Leblic (1988a, 1988b and 1994) documented the use in the area of Montes de Toledo of *Artemisia absinthium*, *Lavandula latifolia*, *Verbena officinalis* L. and *Viola odorata* L. Porres et al. (1986) mention the uses for wounds of *Verbena officinalis*

boiled, in the eighteenth century, we have not recorded any medicinal use for this species.

Malaria was still present in the memory of our informants, and they mentioned several remedies when they were specifically asked about this disease. It was prevalent along the Guadiana River in the proximity of Las Tablas de Daimiel and the rice fields in the Azuer River (Fisac, 1905 a). Malaria was treated here by our informants or their parents by administering infusions, or decoctions, of bitter herbs, such as *Bryonia cretica* subsp. *dioica*, *Centaurium erythraea*, *Lupinus angustifolius*, *Lupinus micranthus* or *Genista tridentata*, or of seeds (*Lupinus albus*), or roots (*Fraxinus angustifolia*). Adams et al. (2011) mention *Centaurium* and *Fraxinus* species among the remedies for malaria in the European herbals of the sixteenth and seventeenth centuries, but not *Lupinus albus*.

It is striking how many antimalarial remedies were used in Ciudad Real area in the 18th century. These included some of species recorded during our study for the same use: *Bryonia cretica* subsp. *dioica*, *Centaurium erythraea*, and *Genista tridentata*; but also others.

Genista tridentata was used to treat “*las calenturas del paludismo*” (= malaria fever) in San Pablo de los Montes, in the 18th century (Porres et al., 1986), and we documented the persistence of this use, two centuries later, in the adjacent town of Alcoba.

Other anti-malarial species used in the 18th century were: *Artemisia absinthium*, *Centaurea ornata*, *Chamaemelum nobile*, *Cichorium intybus*, *Cinchona calisaya* Wedd., *Petroselinum crispum* and *Scorzonera hispanica* (Al-Balatitha et al., 1985; Porres et al., 1986). Leblic (1988a) mentions in Navahermosa, the use of *Artemisia vulgaris* L. against intermittent fevers. We did not record these uses in our interviews.

Helminthiases were only registered in our research in Alcoba and San Pablo de los Montes, treated with *Thymus zygis* or *Lavandula stoechas*, and Leblic (1988b) mentions *Artemisia absinthium* L. and *Lavandula stoechas* in the preparation of anthelmintic remedies. Scabies was treated with decoctions of the leaves of *Rumex* in the area of Montes de Toledo (Leblic, 1988b), once again, this pathology was not registered in our interviews.

Fig. 5 approx. here.

Numerous remedies were documented for menstrual pain and menstrual disorders. Surprisingly, we did not record any remedy for complicated delivery in childbirth, but to induce abortion we documented numerous resources, such as the use of decoctions of *Adiantum capillus-veneris*, *Ceterach officinarum*, *Petroselinum crispum* and *Quercus x morisii* (Table 5). The abortifacient use of *Ceterach officinarum* was also recorded by Ciudad (1985) in the area of Montes de Toledo. Oliver (2018) registered the use to assist delivery of olive oil, almond oil (*Prunus dulcis*), saffron (*Crocus sativus*), lavender (*Lavandula latifolia*), mallow (*Malva sylvestris*) or rockrose (*Cistus ladanifer*) decoction, among others. Nevertheless, we for these species did not documented these but other different uses. In Montes de Toledo, Leblic (1994) recorded the use of *Lonicera periclymenum* seeds macerated in wine to ease delivery and the application of decoctions of rue (*Ruta* sp.) to soften the breasts and facilitate breastfeeding.

Scorpion stings are treated with numerous ingredients, being the most impressive the oil of frying the scorpion itself, which is also recorded by González and Vallejo (2013a) in their review. Blanco (2004) recorded in Nava de Estena the direct application of the bulb of *Drimia maritima* and, in Navalucillos, of the roots of *Asphodelus* sp. pl. Leblic (1988b) registered this last use in Montes de Toledo. We also documented the use to treat scorpion stings of *Asphodelus aestivus*, garlic (*Allium sativum*), *Eryngium campestre* leaves, and *Bryonia cretica* subsp. *dioica* roots. In addition, our informants mentioned the use of *Ruta montana* as a repellent for scorpions and snakes, and the roots of *Eryngium campestre* as a deterrent for scorpion stings (Table 5). Leblic (1994) recorded bay leaves used to treat snake and dog bites. We did not find any of these uses in our interviews.

The use of *Hedera helix* L. was recorded by Leblic (1994) to cure cutaneous abscesses, furuncles and carbuncles, we did not record any use of *Hedera helix*.

Poultices made with several *Rumex* or *Hyoscyamus* species, or with *Solanum nigrum* were used in Nava de Estena (Blanco, 2004). We recorded for such pathologies the use of *Hyoscyamus niger*, *Solanum nigrum*, honey and wheat flour, mustard (*Sinapis alba*), teas of *Paronychia argentea*, and tomatoes (*Lycopersicon esculentum*) (Table 5). For eczema and rashes Leblic (1988b) mentions the use of raw *Asphodelus* roots directly applied, rubbed, we found this use in Alcoba, Horcajo and Nava de Estena.

Warts were treated in Montes de Toledo (Leblic 1988a and 1988b) with *Arum italicum* Mill., or ashes of grapevine shoots, and corns and calluses also with *Arum italicum* Mill. We recorded the use for warts of *Euphorbia characias* and *E. serrata*, holm oak (*Quercus rotundifolia*) leaves, and fig-tree (*Ficus carica*) latex. For corns we recorded the use of *Umbilicus rupestris* and *Plumbago europaea*. Chilblains were cured in Montes de Toledo with ashes of figs (*Ficus carica*) mixed with lard (*Sus domesticus*) (Leblic, 1994). We recorded the use of *Umbilicus rupestris* leaves and walnut (*Juglans regia*) leaves for the same purpose. Arauzo et al. (2001) recorded the use in Villarrubia of the oil in which the leaves of *Ecballium elaterium* A.Rich. were fried, as a topical anti-inflammatory, and of the leaves of *Heliotropium europaeum* L. to treat warts.

We recorded numerous remedies for cardiovascular diseases, however, these were not those reviewed by Mota (2016), but other plants that lack acute toxicity (*Centaurium erythraea*, *Paronychia argentea*, *Paronychia echinulata*, *Phlomis lychnitis* and *Rosmarinus officinalis*). We documented the use of *Paronychia argentea* or *Olea europaea* teas to treat hypertension (Table 5). Leblic (1988b) mentions the antihypertensive use of *Rumex acetosella* subsp. *angiocarpus* (Murb.) Murb., which we did not register. Arauzo et al. (2001) recorded in Villarrubia the use for circulatory diseases of water where it was macerated *Urtica dioica* L.

Our interviewees cited hemorrhoids with a relatively high frequency (Fig. 5). We recorded for the treatment of hemorrhoids the use of *Populus alba*, *Solanum tuberosum*, cold water, wheat milk (*Triticum aestivum*), bark of oak (*Quercus rotundifolia*), galls of *Quercus faginea*, buds of *Cistus ladanifer* and bulb of *Drimia maritima*. The most notable local anti-hemorrhoids is the *Drimia maritima* bulb, its use is also registered by Rojo (2011). Leblic (1994) records the antihemorrhoidal use of *Artemisia vulgaris* and *Mentha pulegium*.

We recorded the use of *Ruta montana* and *Coriandrum sativum* in cases of epilepsy (Table 5). Epilepsy and seizures were treated in Montes de Toledo using *Artemisia vulgaris*, *Drimia maritima*, *Laurus nobilis* L. or *Ruta montana* (Leblic, 1988b, 1994). Sedative teas were prepared with *Papaver rhoeas* petals or marshmallow in the Montes de Toledo (Leblic, 1988b) instead we recorded the use of *Melissa officinalis*, *Mentha pulegium*, *Phlomis lychnitis*, and *Crataegus monogyna*.

Leblic (1988b) list among the remedies for rheumatism *Borago officinalis*, *Cynodon dactylon*, and *Verbena officinalis*. We documented the use for the same

purpose of *Cervus elaphus*, *Malpolon monspessulanus*, and baths in carbonated water, *Urtica urens*, and brandy (Tables 1, 3 and 5).

Acorns are consumed to treat dysentery and colitis, here (Table 5), and in the adjoining provinces also (García and Pereira, 2013; Rojo, 2011). Other remedies of this type are a decoction of *Centaurium erythraea*, myrtle or peony leaves recorded by Leblic (1988b) and of *Althaea officinalis* leaves (Leblic, 1994). For this last species we have documented the use of roots not leaves (Table 5). Rojo (2011) mentions the use of unripe almonds or candied *Cydonia oblonga* fruits for colitis, we did not register medicinal uses for this last species. Arauzo et al. (2001) recorded in Villarrubia the use of *Rubus ulmifolius* fruits macerated in aquavit for abdominal pain.

There were also numerous remedies for diseases of the teeth / gums (Fig. 5). Some such as *Nicotiana tabacum* or *Cannabis sativa* (Table 5) are well-known acclaimed analgesics for oral medicine (Colvard et al., 2006). Others, such as *Crocus sativus*, *Marrubium* and *Hyoscyamus*, *Malva sylvestris*, *Papaver somniferum*, *Pistacia lentiscus*, honey, vinegar and spirits (Table 5), are widely used in Castilla-La Mancha (Verde, 2002), Andalucía (Benítez et al., 2010) and Murcia (Obón and Rivera, 1991). Finally, some are little known outside this area, such as gypsum (Table 3), *Euphorbia serrata*, *Juniperus oxycedrus* or *Tribulus terrestris* (Table 5). Leblic (1988b) recorded from Montes de Toledo the practice of burning *Asphodelus* stems to ashes and placing, on sore molars, balls made with these ashes.

We were surprised when several independent informants told us the use of some drops of a pesticide used in animal husbandry, known as Zotal™ (a mixture of biphenyl-2-ol 3%, chlorophene 1.5%, naphtha, solvents and excipients, add a sufficient quantity to make 100%), which is a strong biocide, to treat decaying teeth.

Leblic (1988b) lists numerous remedies for urinary retention, cystitis or urinary calculi using chicory, *Allium porrum*, *Asparagus acutifolius*, *Ceterach officinarum*, *Cynodon dactylon*, *Genista tridentata* or *Polygonum aviculare* L. We did not find most of these uses among our informants, except for *Cynodon*, instead we recorded the use of *Phlomis lychnitis*, *Paronychia argentea*, and *Silybum marianum* (Table 5).

Fever is treated administering decoctions or teas of *Paronychia argentea*, *Centaurium erythraea*, *Marrubium vulgare*, or *Phlomis lychnitis*. Porres et al. (1986) list as febrifuge other species such as chicory (*Cichorium intybus*), chamomile

(*Matricaria chamomilla*) or *Artemisia absinthium*. Leblic (1988b) mentions *Taraxacum obovatum*.

Leblic (1988b) records the decoction of *Plantago* to treat conjunctivitis. We record the use of *Paronychia argentea*, *Anthemis arvensis*, *Chamaemelum nobile*, *Matricaria chamomilla*, and rosemary (Table 5).

In general, the pathologies recorded here represent a broader repertoire with respect to the range provided by previous studies in this and in neighboring areas. In general, many of the diseases previously reported in ethnobotanical and anthropological studies were also recorded in our interviews, although there were disparities in the species used and treatments.

3.2.2 Broad-use categories

Regarding the selection of species of pharmacological interest, Staub et al., (2015) applied a system of categories of general use to the classification of pathologies. Following this approach, aimed at the development of medicines derived from plants (and animals or minerals), the most frequent categories registered in the Upper Guadiana area were: respiratory diseases, gastrointestinal problems and dermatological disorders (Fig. 6).

Among the prominent species, due to the diversity of their uses, within one or several categories of wide use are some well-known: *Apis mellifera*, *Rosmarinus officinalis*, *Olea europaea*, *Malva sylvestris*, *Glycyrrhiza glabra*, *Papaver somniferum* or *Centaurium erythraea*. Others such as *Paronychia argentea*, *Phlomis lychnitis* or *Genista tridentata* are less known (Fig. 6). The anti-hemorrhoid use of a highly toxic *Drimys maritima* deserves further study.

Dermatological uses of *Achillea ageratum*, respiratory of *Genista tridentata*, gastrointestinal of *Thymus mastichina*. *Ruta montana* and *Phlomis lychnitis*, sedative of *Phlomis lychnitis*, and cardiovascular of *Paronychia argentea* merit further investigation (Fig. 6; Tables 1 and 5). *Achillea ageratum* was shown in previous studies to supply extracts with cytostatic (Gómez et al., 2001), anti-inflammatory (Gómez et al., 1999) and antimicrobial (El Bouzidi et al., 2012) activities. Herrera et al. (1992) have shown the mechanism of antispasmodic activity of the isoflavone genistein extracted from *Genista tridentata*. *Phlomis lychnitis* extracts presented antioxidant (López et al., 2010) and anti-inflammatory (Algieri et al., 2013) activities.

Fig. 6 approx. here.

Paronychia argentea reduced and prevented the growth of urinary stones in rats (Bouanani et al., 2010) however the active compounds are not yet identified. Sait et al. (2015) related the strong antioxidant activity of *Paronychia* extracts to the presence of a series of flavonoids. However, we did not trace any study of the cardiovascular properties of *Paronychia argentea* extracts.

Cutillas et al. (2018) investigated the antioxidant, anti-enzymatic and antimicrobial bioactivities of *Thymus mastichina* essential oil. Azzaza et al. (2016) verified that *Thymus mastichina* essential oil was a main scavenger of nitric oxide (NO) radicals. This and others of the above species deserve a European Union herbal monograph (formerly known as Community herbal monograph). These monographs contain the Committee on Herbal Medicinal Products scientific opinion on safety and efficacy data about an herbal substance and its preparations intended for medicinal use (EMA, 2019).

3.3 Ingredients

3.3.1 Species, substances and uses

Two hundred and twenty species and substances furnishing ingredients have been recorded from the interviews (Tables 1 to 5), of which most are plants (Fig. 7).

Plants stand out for their number of species that quadruples the group that follows them (animals) and for the number of uses (9 times) and records (15 times). However, the total number of pathologies is only 3.7 times that of those treated with animals (Fig. 7). This suggests that the abandonment of resources of animal origin is occurring more rapidly than that of plants, in recent times. Thus the lower number of records.

Fig. 7 approx. here.

It is relevant to notice that ingredients analyzed here were mainly those employed in conventional formulations administered topically, orally or as inhalation, not those merely used for rituals, even if these were with curative purpose. However, there were some (*Aesculus hippocastanum*, *Cervus elaphus*, *Cupressus sempervirens*, *Drimia maritima*, *Ruta montana*, lignite) simply carried or stored, especially in the pockets of

clothing, with the purpose of preventing or curing different pathologies and traumatism (Tables 1, 3 and 5).

Also it is relevant to mention that in the area our informants recognized as toxic several plant species such as *Nerium oleander*, *Paeonia broteri*, *Paeonia officinalis* L. and, finally *Taxus baccata* L., although some had local medicinal uses.

These ingredients belong to 87 different families of plants, animals and fungi and categories of mineral substances and synthetic chemicals. The most relevant in number of records, uses and species are Lamiaceae and Compositae (Fig. 8). Rosaceae present more species than Leguminosae and Malvaceae families, but are almost doubled by Leguminosae and Malvaceae in number of uses and records (Fig. 8). This recall us the debate on the differential ethnopharmacological relevance of plant families raised by Moerman (2003) and Weckerle et al. (2011).

Fig. 8 approx. here.

Formulations documented are presented by each one of the ingredients classified by kingdoms, families and species, in tables 1 to 5. Information includes: provenance, habitat, locality, part, preparation, and administration, standardized pathology (ICD-10, ICPC 2e7.0, and Broad Use). Additionally original spelling of Spanish names of ingredients and pathologies is retained in Tables 1 to 5 to facilitate comparison with other ethnographic sources.

Malva sylvestris, *Phlomis lychnitis*, *Genista tridentata* and *Thymus mastichina* are the ingredients more frequently recorded (Table 6 and Fig. 9). These are closely followed in number of records by *Thymus mastichina* subsp. *mastichina*, *Olea europaea*, *Paronychia argentea*, *Rosmarinus officinalis*, *Achillea ageratum*, and *Mentha pulegium*.

Fig. 9 approx. here.

3.3.2 Medicinal uses of animals and fungi

We determined the local use of leeches for hidradenitis suppurativa and hematoma in the 20th century (Table 1). During the 16th century the use of leeches was far more common in official medicine, and those from Torre de Juan Abad (southern Ciudad Real) were much prized (Campos, 2009). The presence of leeches in Tablas de Daimiel is confirmed by Muñoz and Soriano (2012). The leeches of Torre de la Higuera springs

of Villamanrique, 2 km from the Torre de Juan Abad were recognized at the time as singular: “it has leeches painted with dark and white and green wheels, and these leeches have such a virtue that any person who has suppurative abscesses in any part of the body ... heals the person of that abscess...doctors say that there are only of these leeches two sources throughout Africa and Europe” (Campos, 2009). This seems to correspond to *Hirudo troctina* instead of *H. medicinalis* (Linnaeus 1758) (cf. Utevsky et al., 2009; González and Vallejo, 2013b; Vallejo and González, 2015) or it is an extinct species. Note that they say “And in the other source that is next to where these leeches are, there are many leeches of the commons and there are none like those of the other source, nor do they have any virtue like the others, both sources being close together”. Thus, two different types of *Hirudo* were recognized with notable differences in efficacy.

Table 1 approx. here.

The use as a counter-poison of *Berberomeloe majalis* is an interesting record (Table 1), however we did not obtain the information on which specific poisoning was treated with the poison of this beetle. Percino et al. (2013) has not reported this use. González and Vallejo (2013b) reported dermatological use of secretions of this insect to burn warts.

Donkey milk is recorded here as a remedy for cough and this use is not included in the review by Vallejo and González (2014) on the role of equidae in ethnomedicine in Spain. The practice of frying the hair of a rabid dog and rubbing the oil on the bite in order to prevent rabies in humans is documented by Quave et al. (2010).

The medicinal uses of fungi in the Upper Guadiana area is reduced exclusively to the spores of Agaricaceae and Sclerodermataceae (Table 2).

Table 2 approx. here.

3.3.3 Medicinal uses of mineral substances

Nine medicinal resources of mineral origin were documented (Table 3).

Baths in the *hervideros*, of carbonated water were reported by physicians of the 19th and 20th centuries useful to treat herpesviral infections and mycobacteriosis, syphilis, rheumatism and other pathologies (Torres, 1821) we recorded among our informants their use in cases of rheumatism and diseases of the skin (Table 3).

Table 3 approx. here.

We recorded the use of salt to treat stomatitis, open wounds and sprain and strain of ankle (Table 3). Salt is used in Manzanares to cure warts and hordeolum (stye) (Martín, 2008). Styes (bacterial infection of an oil gland in the eyelid) are washed with chamomile tea and magically treated by passing threefold a gold ring (Martín, 2008). We were not able to document from our informants remedies for hordeolum.

Table 4 approx. here.3.3.4 *Medicinal uses of plants***Table 5 approx. here.**

Malva sylvestris, *Phlomis lychnitis*, *Genista tridentata*, *Thymus mastichina* subsp. *mastichina*, *Olea europaea* (wild and cultivated), *Paronychia argentea*, and *Rosmarinus officinalis* as said before are the more often used species (Table 6).

Table 6 approx. here.

We comment in the following paragraphs the discrepancies between our records and those from other sources referring to the research area and neighboring zones. We also include coincidences recorded from other areas of Spain and Portugal.

Malva sylvestris, especially its flowers, is widely used for common cold, pneumonia, acute bronchitis, acute periodontitis, constipation, abdominal pain, myositis, contusion, burns and corrosions, pimples, cutaneous abscess, furuncle and carbuncle, wounds, headache, and edema (fluid retention). Rojo (2011) mentions its use as a digestive. In the Mediterranean region is as remedy for numerous diseases especially due to the presence of flavonoids and mucilage (Gasparetto et al., 2011).

The presence of *Phlomis lychnitis* in western Iberian Peninsula is rare, occurring on isolated calcareous upwelling, however it is widely used there for medicinal purposes: malaise in Sao Mamede (Camejo et al., 2003), dyspepsia, urinary tract dysfunctions, pain and edema in Arrabida (Novais et al., 2004). Pardo et al. (2005) recorded the uses of *Phlomis lychnitis* for dyspepsia and nervousness. *Phlomis lychnitis* extracts displayed intestinal anti-inflammatory activity in experimental colitis in rats (Algieri et al., 2013). We recorded its use to treat common cold, fever, digestive diseases in general, abdominal pain/cramps, dyspepsia / indigestion, nausea, atherosclerosis s/ peripheral vascular disease, headache, vertigo / dizziness, paralysis / weakness, anxiety,

acute stress reaction, other psychological symptoms, upper respiratory infection and urinary retention.

Thymus mastichina is widely used by our informants for burns and corrosions, wounds of unspecified body region, rheumatism, common cold, cough, diseases of the digestive system, gastric ulcer, functional dyspepsia, abdominal and pelvic pain, nausea and vomiting, malaise and fatigue, and localized edema (feet). Rojo (2011) recorded its digestive use. Its extract presented high antioxidant activity (Delgado et al., 2014).

Paronychia argentea is a well-known panacea species, used for scarlet fever, conjunctivitis, hypertensive diseases, atherosclerosis, varicose veins of lower extremities, diseases of the circulatory system, common cold, acute pharyngitis, cutaneous abscess, furuncle and carbuncle, urticarial, pimples, wounds, calculus of kidney, renal colic, retention of urine, irregular menstruation, unspecified, abdominal and pelvic pain, dizziness and giddiness, fever and pain. Carmona et al. (2005) documented numerous uses of *Paronychia argentea* in different Mediterranean countries, and its presence in the *Zahraa* or *Zhourat* herbal mixture (Obón et al., 2014). Rojo (2011) recorded its dermatological and anti-allergic uses. Another local panacea is *Genista tridentata*, which also has many uses in Portugal. This species, with high levels of total phenolic compounds, shows significant antioxidant activity (Coelho et al., 2011). *Althaea officinalis* is used to treat endocrine and metabolic diseases, upper respiratory infections and bronchitis; the roots contain mucilage, flavonoids and glycosides (Shah et al., 2011).

Elderflower is here used for treating common cold, localized edema, wounds, myalgia, contusions, burns and corrosions. Rojo (2011) registered the analgesic and anti-inflammatory uses. The analgesic use of *Sambucus nigra* leaves is also recorded in Navarra (Calvo and Cavero, 2016).

Porrás et al. (1986) mention the use in the 18th century of *Anethum graveolens* L., fruits, in teas for flatulence. Leblic (1994) documented the use of *Artemisia vulgaris* L. for abdominal pain, and of *Amaranthus deflexus* L., for dyspepsia. We did not record any use for these species. However it is possible that Leblic (1994) misidentified *A. verlotiorum* in the sense of *A. vulgaris*.

Cucumber macerated in brandy is used to treat abdominal pain, this is also documented by Blanco (2004) from the Montes de Toledo area.

We recorded the use of *Arbutus* root decoction to treat syphilis and common cold among others. Antibacterial, antifungal and anti-parasitic activities of *Arbutus unedo* extracts were reviewed by Morgado et al. (2018) however there is no evidence of activity against *Treponema pallidum*. Anthocyanins and flavonoids are the major active substances in roots of *Arbutus* (Morgado et al., 2018).

Achillea ageratum is the “arnica” of the Upper Guadiana basin (Obón et al., 2012), here is used to treat common cold, functional dyspepsia, myositis, pimples, pain, wasps bites, open wounds and contusions. However, its documented biological activities are scarce in relation with other yarrow species (Nemeth et al., 2008).

Centaurea ornata is widely used in the area to treat urticarial and pimples, and to cure wounds, even when infected (Table 5). Vallejo et al. (2009) recorded these and other uses in Badajoz raising the concern of misidentification and confusion with the toxic species *Chamaeleon gummifer* (L.) Cass. Though, seemingly, this last species is not reported from the province of Ciudad Real (Anthos, 2018) the danger is lesser.

It is worth to notice here that digestive teas named “tê” are, in Cabañeros, not only *Artemisia verlotiorum* but also *Bidens aurea*. Both are naturalized alien species, presumably escaped from herb gardens during the 20th century. The former (*A. verlotiorum*) was introduced from China (James et al., 2000) and the latter (*B. aurea*) from Central America (Di Castri et al., 1990). Blanco (2004) and Rojo (2011) recorded the use of this last species in Montes de Toledo and López-Nieve et al. (2012) in Los Pedroches (Córdoba) as a sedative and digestive herbal tea. *Anthemis arvensis* is used in teas for anxiety disorders, conjunctivitis, common cold, functional dyspepsia, and flatulence and related conditions. Rojo (2011) recorded the use of this species in San Pablo de los Montes as a digestive. We recorded the use of *Matricaria aurea* to treat common cold and Rojo (2011) for conjunctivitis. A decoction of *Helichrysum stoechas* is used externally to treat burns and corrosions and orally administered for abdominal and pelvic pain. Rojo (2011) recorded its use as a digestive.

Pardo et al. (2005), in their review of plants known as tea in Spain, recorded the use of *Mentha aquatica* for dyspepsia but not for menstrual pain (Table 5). Rojo (2011) mentions its use as a digestive. *Mentha pulegium* is widely known and used for common cold, varicose veins, gastric ulcer, functional dyspepsia, abdominal and pelvic pain, nervousness and urticarial. Rojo (2011) recorded its use as a digestive and for abdominal pain. Local substitutes for pennyroyal are *Mentha cervina* and *Clinopodium*

nepeta. *Thymus zygis* is locally used for common cold, cough, functional dyspepsia, abdominal and pelvic pain, halitosis, dizziness and giddiness, post-traumatic wound infection, and intestinal parasitism. Rojo (2011) recorded its digestive use.

A Bermuda grass (*Cynodon dactylon*) rhizome decoction is here used to cure calculus of kidney and retention of urine, and Rojo (2011) mentions its use for rheumatism. We recorded the use of *Rumex pulcher* infructescences to treat gastroenteritis and colitis, and Rojo (2011) recorded the same use but for wilted flowers. Rojo (2011) recorded the use of wild rose leaves, crushed, to alleviate pruritus in children, we only recorded the use of rose hips (*Rosa canina*) to treat colitis.

Although the Rutaceae *Dictamnus hispanicus* Webb ex Nyman and *D. albus* L., grow in the upper part of the Guadiana River and are used in Cuenca and Albacete to treat bronchitis, helminthiasis and diseases of the nervous system (Martínez-Francés et al., 2015) we did not record any use from our informants. *Ruta montana* is another panacea species widely in use here for burns and corruptions, epilepsy, dizziness and giddiness, functional dyspepsia, abdominal and pelvic pain, rheumatism, myalgia, pain in limb, contusions, irregular menstruation, dysmenorrhea, and viper bites. Rojo (2011) recorded its use for fever, rheumatism, and functional dyspepsia, usually macerated in brandy or olive oil.

The use of *Daphne gnidium* bark to cure toothache is also recorded by Rojo (2011).

3.3.5 Provenance of ingredients and habitat of species

Plant parts most often involved in the formulations are flowering aerial parts 36% and roots 9% (Fig. 10). While animals appear with frequency of 1%, as whole animal, or lesser.

Fig. 10 approx. here.

Most records refer to species locally available classified as Mediterranean, European or Widespread (Fig. 11).

Ingredients locally collected in open shrublands, known as “garrigue”, and dry grasslands furnish a relevant proportion of records whereas imported ingredients play a marginal role (Table 7; Fig. 11).

Table 7 approx. here.

The contribution of wetlands, riverine habitats and, especially, watered fields and gardens as a source of medicinal resources is high, 36% of records (Fig. 11), given their

limited presence in terms of total extent within the study area. However, most of the genera typical of the local wetlands (*Carex*, *Cladium*, *Sparganium*, *Cyperus*, *Typha*, *Juncus*, *Scirpoides*, *Bolboschoenus*, *Potamogeton* or *Ranunculus*) (Cirujano and Medina, 2002) are scarcely represented or lacking in the list of medicinal ingredients.

Fig. 11 approx. here.

3.4 *Forms of preparation and administration*

The use of simples and drug formulations in the Upper Guadiana River area mostly involve the preparation of hydrolytes extracted with heat (tea or decoction) which are orally ingested as a drink or externally applied as poultices or washes. However the use of unprocessed raw material is not negligible (Table 8).

Table 8 approx. here

Extraction by frying or maceration in olive oil is also relatively frequent in terms of uses and records (Table 8).

3.5 *Geographical patterns*

Overall, the classification generated through hierarchical cluster using the Ward's minimum variance criterion, based on presence / absence of ingredients presented four groups (Fig. 12 A). A second method of tree building, the weighted neighbor joining, coincides in the four clusters structure (Fig. 12 B). These groups follow a distinct geographical pattern East to West of association for localities:

1. Western group, which clusters the villages of Cabañeros National Park area characterized by a landscape of open *Quercus* woodland on siliceous substrates and acidic bogs, and a very low population density.
2. Transitional group of localities, including Piedrabuena is recognized, with small mountain ranges.
3. The main group in terms of number of localities extends along central Ciudad Real, with two notable areas: Tablas de Daimiel national park and Campo de Calatrava. The area is more densely populated and characterized by the presence of volcano substrates but especially by the abundance of wetlands, lagoons and marshes, scattered or associated to the Guadiana River and its tributaries (Cigüela, Zán cara or Azuer).

4. Eastern group of localities, notably the Lagunas de Ruidera natural park, with open woodlands and grapevine plantations, on calcareous substrates.

This classification reflects the different availability of resources at local level and underlines the adaptive nature of traditional folk-medicine.

The western group presents a higher richness of ingredients, on average 38.8 per locality, followed by the central group with 17.5 ingredients per locality. These are the best characterized with the presence of exclusive species. Notably, *Bidens aurea*, *Sinapis alba* and *S. arvensis*, *Paronychia echinulata*, *Bryonia cretica* subsp. *dioica*, *Clinopodium nepeta*, *Mentha cervina*, *Cynodon dactylon* and *Quercus x morisii*, and others such as *Allium cepa*, *Allium sativum*, *Apium graveolens*, and *Pistacia lentiscus* characterize the western group. It is also characterized by the use of bee products (*Apis mellifera*), *Cervus elaphus*, and scorpions (*Buthus occitanus*) with a higher frequency than in the rest. Other representative species, shared with the central group, are *Achillea ageratum*, *Asparagus acutifolius*, *Centaurea ornata*, *Cuminum cyminum*, *Drimia maritima*, *Foeniculum vulgare*, *Malpolon monspessulanus*, *Pimpinella anisum*.

The central group, around Daimiel, uses animals such as *Ardea cinerea*, leeches (*Hirudo troctina*), *Mantis religiosa* and *Malpolon monspessulanus*. Characteristically it presents the use of plant species such as *Beta vulgaris*, *Alkanna tinctoria*, *Juglans regia* or *Mentha × rotundifolia*.

The eastern group is poor in species, on average 7.3 per locality. *Teucrium pseudochamaepitys* and *Althaea officinalis* (this last shared with the central group) are characteristic.

The transitional southwestern group is the poorest in species recorded, on average 6 per locality, characterized by the use of *Genista tridentata*, which is also distinctive of the western group.

This methodology for comparison between localities based on the ingredients used in the formulation of medicines has previously been used by Rivera et al. (2017 and 2019). However the classification obtained here is much clearer. The reason is the use here of a minimum threshold of ingredients per locality and of localities per ingredient, which reduces noise in the calculation process.

Three localities cluster outside the groups of their region. Fuencaliente clusters with the group of Piedrabuena and neighboring (transitional southwestern group) (Fig. 12 A and B) although the locality is geographically to the north somewhat separated from it.

Its location is, physically but also in terms of used resources, intermediate, between El Robledo (western Cabañeros group), with which it shares *Genista tritentata*, and Malagón (central Daimiel group) with which it shares *Malva sylvestris*. Therefore, this would explain its presence in the southwestern transitional group that alternately shares species with one or the other.

Las Mesas (eastern group, Fig. 12 B) shares the medicinal use of *Sambucus nigra* and *Triticum aestivum* with the central and western groups, *Prunus cerasus* with the western group, and *Solanum tuberosum* with the central group. Las Mesas is assigned to the central group in the Ward's tree (Fig. 12 A). The use of *Althaea officinalis* was not recorded in La Solana nor in Las Mesas (Table 5) in what they differ from the rest of localities of the eastern group. La Solana (eastern group, Fig 12 A) shares the use of *Mentha pulegium*, and *Phlomis lychnitis* with the central and western groups. La Solana is assigned to the central group in the neighbor joining tree (Fig. 12 B). Given the scarce number of species recorded in Las Mesas and La Solana, seven and eight respectively, the above peculiarities explain their eventual displacement in the clusters depending of the method followed to generate the tree (Fig. 12 A and B).

Fig. 12 approx. here

3.6 Relationships with historical evidence for Upper Guadiana area

Thymus mastichina, dill (*Anethum graveolens*), rosemary (*Rosmarinus officinalis*), lavender (*Lavandula latifolia*), *Lavandula stoechas* and *Teucrium* were part of a mixture used in Montes de Toledo during late 16th century to treat rheumatism (Blázquez, 1989). Ophthalmic remedies are documented in the area since the 17th century, based on *Globularia alypum* L. (Blázquez, 1985 and 1989; Longobardo et al., 1997), or a mixture of *Chelidonium majus* L., rue, myrtle, saffron, rosemary and roses (Blázquez, 1985 and 1989).

Campos (2009) reported in the *Relaciones de los pueblos* of Felipe II (16th century), for localities of present Ciudad Real province, the use of *Hirudo troctina* and he cites the use of numerous medicinal waters, either drinking or bathing in them (Table 9). We recorded the last remnants of this traditional use of medicinal waters within local population (Table 3) and, also, *Hirudo troctina* uses (Table 1). Recently, baths of “*El Hervidero*” in the vicinity of the ruins of Calatrava la Vieja (Carrión de Calatrava), were restored to make their use available to local population and tourism.

Table 9 approx. here

These *Relaciones* did not contain any information on medicinal plants unlike those of Chinchilla or Yeste in the neighboring province of Albacete (Rivera et al., 2017).

The *Descripciones del Cardenal Lorenzana*, 18th century, describe springs and water upwelling scattered in different villages and employed to treat dyspepsia, intestinal obstruction and flatulence which were still important (Table 10). Others were used for herpesviral infection, scabies and rheumatism (Al-Balatitha et al., 1985; Porres et al., 1986).

Table 10 approx. here

The use of cantharides is no longer recorded in our interviews (Table 1). Additional medicinal resources mentioned in the *Descripciones* include numerous antimalarial plant remedies and others for wounds (*Anthyllis vulneraria*), rheumatism (*Genista tridentata*), respiratory (*Brassica oleracea*, *Cuminum cyminum*) and digestive complaints (*Nicotiana rustica*, *Olea europaea*). During the 18th century decoctions of henbane (*Hyoscyamus*) or *Cynoglossum cheirifolium* L. were administered to treat pain (Porres et al., 1986). Only a small part of these uses persisted in our records (Table 5).

Porres et al. (1986) mention the use, in the 18th century, of bramble shoots to prepare a decoction to rinse oral cavity to cure sores, we found this use in Horcajo and Navalpino.

Fisac (1905a) in his “*Topografía Médica de Daimiel y su partido*” reports medicinal plant species and their uses in Daimiel (Table 11).

Table 11 approx. here.

Some of these were at the time a relevant source of income for dwellers of the wetlands zone. They collected, dried and exported *Althaea* roots or *Malva sylvestris* and *Papaver rhoeas* petals. *Althaea officinalis* roots were later exported, for instance from Villarrubia de los Ojos to the pharmacies of Valencia and Reus (Arauzo et al., 2001). *Malva sylvestris* is so far the most relevant plant species in the Guadiana area (Tables 5 and 6) and *Althaea officinalis* is widely used. The uses of *Papaver rhoeas* are presently restricted in the area to the treatment of insomnias, nervousness and acute bronchitis (Table 5).

The uses and species recorded in Table 11 are extremely interesting, since they suppose precedents of the records of our study. The use of fungal spores to heal wounds persisted a century later (Table 2) but, instead of *Calvatia*, we recorded *Lycoperdon perlatum*. Another interesting warning given by Fisac (1905a) is the existence in Daimiel of healers who used plants for magical practices.

Drimia maritima was reported as a diuretic, expectorant, and emetic (Fisac 1905a) we recorded its use for the treatment of hemorrhoids, hidradenitis suppurativa and pimples (Table 5) therefore there is no one coincidence in the uses. Have the local uses so deeply evolved within a century? Or is there some misidentification? However it is well-known the Squill Oxymel use for the treatment of asthma (Nejatbakhsh et al., 2017) therefore despite the toxicity of this plant the reference by Fisac (1905a) is likely right.

Cytisus scoparius, *Filipendula vulgaris*, *Scorzonera hispanica* are species no longer recorded as medicinal resources in our interviews (Table 5) although we cannot neglect the possibility that these were misidentified by Fisac (1905a).

In general, the historical evidence analyzed suggests the continuous presence in the area of healing practices, within the framework of popular medicine, which implies the use of local resources. Some of these were related to harvest activities and handling of raw medicines exported to pharmacies located in the large cities of Spain. Given the fragmentary nature of the available historical evidence, most of the uses recorded in our fieldwork (Tables 1 to 5) were not in the historical records (Tables 9 to 11). Other species and uses so far persisted and, finally, some disappeared.

4 Conclusions

The above analysis gives rise to a range of immediate and far-reaching conclusions relevant to ethnobotanists and ethnopharmacologists: Malaria is still present in the memory of our informants and was treated with *Centaurium erythraea*, *Lupinus albus* and *Fraxinus angustifolia*, however, in the Upper Guadiana the more frequent pathologies were respiratory (acute nasopharyngitis) and gastrointestinal problems which were treated with a wide range of simple or compound remedies involving numerous species of notably plants, animals and mineral substances.

The most documented species are *Malva sylvestris*, *Phlomis lychnitis*, *Genista tridentata* and *Thymus mastichina*, and the habitats where these plants were harvested

were dry woodland and grassland. Almost all medicinal species are local and of Mediterranean origin. A geographical pattern is detected from east to west in the list of ingredients used in each locality with two main centers: Cabañeros-Montes de Toledo and Daimiel-Campo de Calatrava. We found strong differences with other local sources analyzed in terms of resources and pathologies especially in the area of Montes de Toledo.

The wide-ranging ethnographic databases such as those we used are difficult to adapt for specialized ethnopharmacological research because the work of data cleansing requires much time, instead, it is advisable to use more specific tools. Therefore, the use of databases adapted for exclusively ethnopharmacological purposes is more sensible and recommendable.

Along the Guadiana River in the Ciudad Real province exists a wide and deep knowledge of traditional remedies for common pathologies, based fundamentally on the use of local flora, fauna and mineral resources. The uses and ingredients documented are useful for further pharmacological investigation to improve health care for a wide range of pathologies.

According with the results of the present study, we strongly recommend that ethnopharmacological studies in the future should include all ingredients actually used by the informants independently of their origin, not only plants. Ethnopharmacological studies restricted exclusively to plants, according to our data, miss nearly 15% of ingredients and misinterprets at least a 10% of uses.

5 Acknowledgements

We would like to thank Dr. Bernat Vanaclocha for granting full access to the Fitoterapia.net database, and the directors of the national parks of Cabañeros and Tablas de Daimiel (Organismo Autónomo de Parques Nacionales) for their help. This study is part of the project Etnobiología de los Humedales en los Parques Nacionales de Tablas de Daimiel y Cabañeros. Ref: 1659/2015 Organismo Autónomo Parques Nacionales.
